Julian Garcia CSE 344 HW 1

I certify that every answer in this assignment is the result of my own work; that I have neither copied off the Internet nor from any one else's work; and I have not shared my answers or attempts at answers with anyone else.

1. Consider a sorting algorithm EVENTUALSORT, whose pseudo-code is given below.

```
EVENTUALSORT(A)
    n \leftarrow A.length
    for i \leftarrow 1 to n-1 do
         j \leftarrow i
         while j ≤ n − 1 do
4
5
              j \leftarrow j + 1
              if A[i] > A[j] then
6
7
                    \triangleright now swap A[i] with A[j]
8
                    EXCHANGE(A, i, j)
9
                    i \leftarrow i
```

Its only input $A[1 \cdots n]$ is an array of n elements which can be compared using >.

Algorithm EXCHANGE, given an array followed by two valid indices as input, swaps the contents of the two corresponding elements. Determine the best-case time complexity of EVENTUALSORT and the worst-case time complexity of EVENTUALSORT. For both cases,

- 1. create a table with three columns: *Line number* (from the pseudo-code), *Cost, Best-case Number of Times / Worst-case Number of Times*;
- 2. fill in appropriate entries: for a sequence, write it out using ellipsis, then in sigma-notation, and finally as a polynomial (state and prove any formula you use to sum those sequences); and
- 3. finally, combine those entries into a closed-form polynomial for T(n), the time taken by EVENTUALSORT. Simplify as much as possible.

Assume a cost of 3 for EXCHANGE and c for all executable statements. Show your steps clearly.

First, establishing what X and Y are:

Let t_j be the #times the while-stmt executes for a particular assignment to the loop variable j. Thus,

$$X = t_1 + t_2 + ... + t_n = \sum_{j=1}^{n} t_j$$

Y =
$$(t_1 - 1) + (t_2 - 1) + \dots + (t_n - 1) = \sum_{j=1}^{n} t_j - \sum_{j=1}^{n} 1$$

Line	Cost	#Times Worst Case	#Times Best Case
1	c_1	1	1
2	c_2	n	n
3	c_3	n-1	n - 1
4	C ₄	Occurs when $t_j = j$ for all j So, in this case:	Occurs when $t_j = 1$ for all j.
		As a sequence: X = 1 + 2 + + (n - 1) + n	As a sequence: $X = 1 + 1 \dots + 1$
		In sigma notation: $X = \sum_{j=1}^{n} j$	In sigma notation: $X = \sum_{j=1}^{n} 1$
		As a polynomial: X = n(n+1) / 2	As a polynomial: X = n
		Proof: Take our sequence: $X = 1 + 2 + + (n - 1) + n$ Reverse that sequence: $X = n + (n-1) + + 2 + 1$ Add these two sequences, term-by-term, each term results in n+1 so: $2X = (n + 1) + (n + 1) + + (n + 1) + (n + 1) = n (n + 1)$ Divide that result by 2: $X = n(n + 1) / 2$	
5	c ₅	Also occurs when $t_j = j$ for all j So in this case:	Occurs when $t_j = 1$ for all j.
		As a sequence: Y = (1 - 1) + (2 - 1) + (n - 1 - 1) + (n - 1) In sigma notation: $Y = \sum_{j=1}^{n} j - \sum_{j=1}^{n} 1$	Y = 0
		As a polynomial:	

		Y = (n(n+1)/2) - n	
		Proof: Take our Sequence: $Y = (1-1) + (2-1) + \dots + (n-1) + (n-1)$ Extract the -1 from each term: $Y = (1+2+\dots+(n-1)+n) - n$ Looking at the proof from line 4, we have already proved that: $(1+2+\dots+(n-1)+n) = n(n+1)/2$ Therefore, $Y = (n(n+1)/2) - n$	
6	c_6	Y = (n(n+1)/2) - n	Y = 0
7	0	Y = (n(n+1)/2) - n	Y = 0
8	3	Y = (n(n+1)/2) - n	Y = 0
9	c ₇	Y = (n(n+1)/2) - n	Y = 0

Best Case:

$$T(n) = c_1(1) + c_2(n) + c_3(n-1) + c_4(n)$$

 $T(n) = \Theta(n)$

Worst Case:

$$\begin{split} T\left(n\right) &= c_1(1) + c_2(n) + c_3(n-1) + c_4(\ n(n+1)/2\) + c_5(\ (n(n+1)/2) - n\) + \ c_6(\ (n(n+1)/2) - n\) + \ 3(\ (n(n+1)/2) - n\) + \ 3(\$$

2. Assuming A, B, and C are non-zero constants and A is positive, prove that

$$An^2 + Bn + C = \Theta(n^2).$$

Let $An^2 + Bn + C$ be represented by h(n)

To prove this, we have to find that there are constants c_1 , c_2 and n_0 such that for all $n \ge n_0$:

$$0 \le c_1 * n^2 \le h(n) \le c_2 * n^2$$

Let $n_0 = 1$

Since $n \ge 1$, we can multiply both sides by n and show that $n^2 \ge n$

Therefore, $n^2 \ge n \ge 1$

And, by the rules of inequalities, $n^2 \ge n^2$

So, we can form the inequality:

$$An^2 + Bn + C \le An^2 + |B|n^2 + |C|n^2$$

Since each term on the right is equal to or greater than the term on the left.

So,

$$An^2 + Bn + C \le (A + |B| + |C|)n^2$$

Now that we now $(A + |B| + |C|)n^2$ is greater than our function we can choose our upper bound value, $c_2 = A + |B| + |C|$

To find our lower bound c_1 : Again, we know that $n^2 \ge n \ge 1$ Multiplying that by -1 we can now see that: $-1 \ge -n \ge -(n^2)$

We also know that An^2 is a positive value, since A is given as positive and non-zero. So, the simplest inequality we can form, given that we don't know the sign of A and B is:

$$An^2 + Bn + C \ge An^2 - |B|n^2 - |C|n^2$$

Since we know that each term on the right is equal to or less than each term on the left So,

$$An^2 + Bn + C \le (A - |B| - |C|)n^2$$

So we can choose $c_1 = A - |B| - |C|$ for our lowerbound.

Therefore, we've found values for n_0 , c_1 and c_2 such that for all $n \geq \ n_0$:

$$0 \le c_1 * n^2 \le h(n) \le c_2 * n^2$$

And we have proven that $An^2 + Bn + C = \Theta(n^2)$
